Diferentes gafas:

Experiencias desde el Observatorio de Salud en Asturias

Planificación de estrategias de salud

Participación comunitaria

Planes municipales de salud

Programa de actividades comunitarias de la
semFYC

Objetivos de la sesión:

1. Exploración y puesta en común sobre la situación actual del trabajo intersectorial en salud y promoción de la salud en el ámbito local.
2. “El código postal influye más en la salud que el código genético”: Revisión general de aspectos relacionados con determinantes de la salud y desigualdades en el ámbito local.
3. Trabajo intersectorial para el abordaje de los determinantes de la salud en el ámbito local. Agenda 21, Ciudades Saludables, Ciudades amigables con los mayores, Smartcities, Ineqcities. ¿es posible conciliar las diferentes estrategias de intervención?
4. Participación y coordinación en intervenciones intersectoriales.

5. Principales ejes para el abordaje de los determinantes de salud desde el ámbito local: actuaciones intersectoriales. Ciclo de intervención para la promoción de la salud en el ámbito local.
6. De la información a la acción: la experiencia inicial del Observatorio de Salud en Asturias. Proporcionando información sobre determinantes de salud para generar actuaciones intersectoriales.
7. Mapas de riesgos de salud y mapas de activos de salud. Los activos de salud como una posibilidad de conectar recursos municipales con la práctica clínica. Metodología para la elaboración de los mapas de activos de salud.
8. Conectando diferentes sectores a través de los mapas de déficits y activos: prescripción de activos de salud.

Documentación de referencia

Documentación complementaria

Taller Intersectorialidad y Promoción de la Salud en el ámbito local.

28 enero 2014

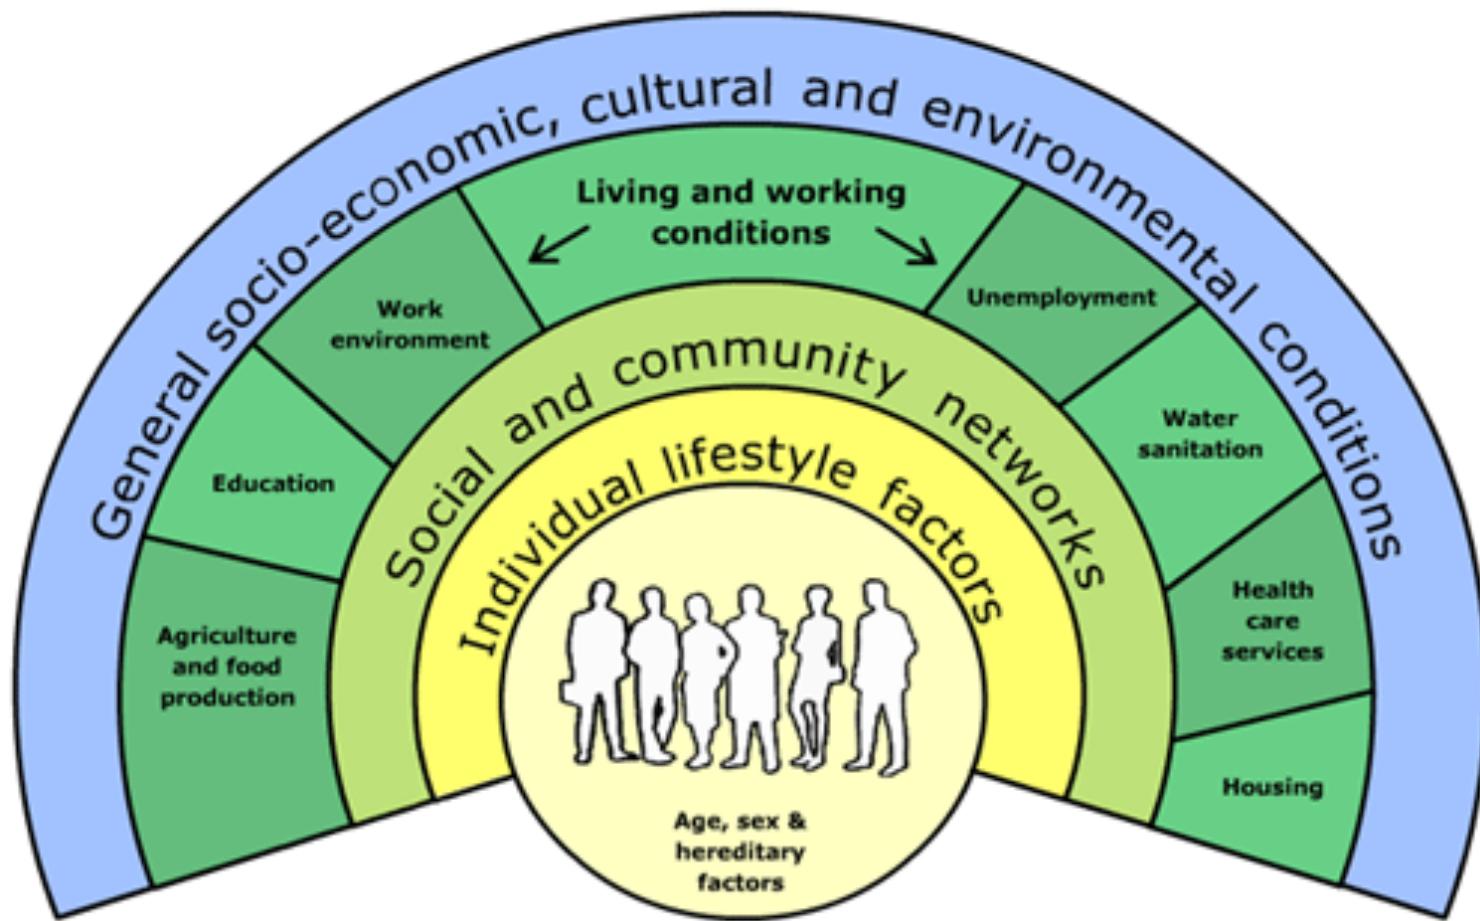

Puntos clave

- La importancia del ámbito local para lograr un impacto en la salud de la población.
- La importancia del trabajo sobre determinantes no clínicos y de actuar desde fuera del sistema sanitario.
- La importancia de las intervenciones poblacionales.
- La necesidad de una mirada en equidad.

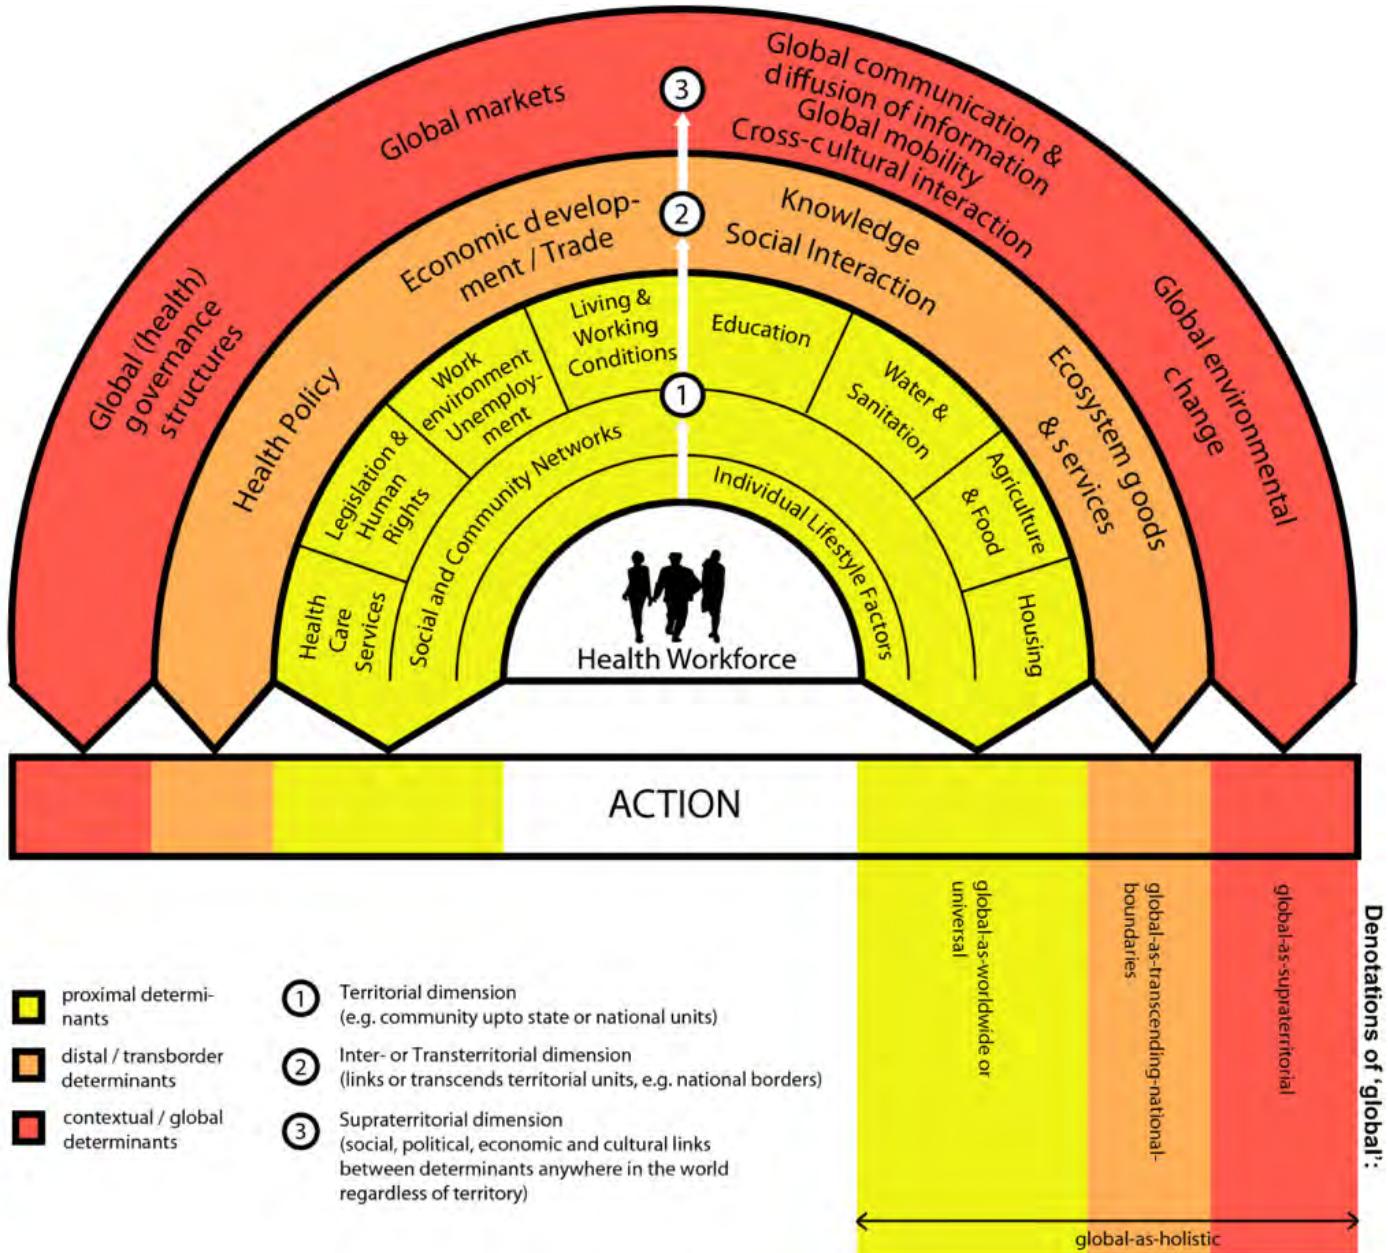

- El trabajo intersectorial y la participación como un elemento central.
- Realizar una aproximación a lo que está pasando en la comunidad con una mirada de problemas y con una mirada de activos en salud.
- Estas miradas pueden ser un punto de encuentro de alianzas entre lo municipal, el sistema sanitario y la salud pública
- Una evaluación integral: la evaluación del impacto en salud.
- Necesidad de tener un proceso estructurado de los siguientes pasos.

¿Qué **factores** influyen actualmente
en el bienestar y la salud de nuestra población ?

FACT

In the United States, 121,750 lives could be saved if 10% more people had some college education.

Want to improve health? Start with where we live, learn, work and play.

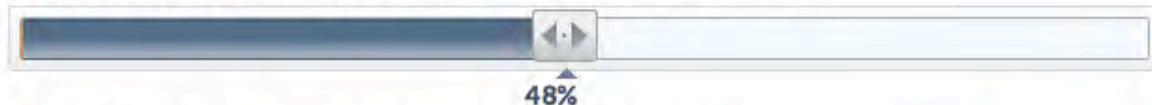

The County Health Calculator is a tool for advocates and policy makers. Health is about more than healthcare. It is about education, income and the environment in which we live. Use the calculator to see how education and income affect health outcomes. Click below to get started.

NEWS

Austerity measures will lead to rise in unemployment and suicides, says Marmot

Matthew Limb

London

European austerity programmes are a “ghastly experiment” that will lead to more citizens’ deaths, says a leading expert on health inequalities.

Michael Marmot spoke about the link between rising unemployment and higher mortality rates, including suicides.

He warned of the effects of government policies in countries such as Spain and Portugal that he said were being pursued at the behest of financial markets and central banks.

“If unemployment rises as a result of government policy that is

But he said child poverty was predicted to rise in the UK under coalition policies. “If you put fairness at the heart of all policy making it wouldn’t do that,” he said.

David Buck, a senior fellow at the King’s Fund, said that life expectancy, one of the main indicators of health inequalities, was still improving in England.

But he said that there remained large inequalities within neighbourhoods and that more research was needed to find out why some areas fared better than others.

Abstract

Background Disadvantaged socio-economic position (SEP) in childhood is associated with increased adult mortality and morbidity. We aimed to establish whether childhood SEP was associated with differential methylation of adult DNA.

Methods Forty adult males from the 1958 British Birth Cohort Study were selected from SEP extremes in both early childhood and mid-adulthood. We performed genome-wide methylation analysis on blood DNA taken at 45 years using MeDIP (methylated DNA immunoprecipitation). We mapped in triplicate the methylation state of

Abstract

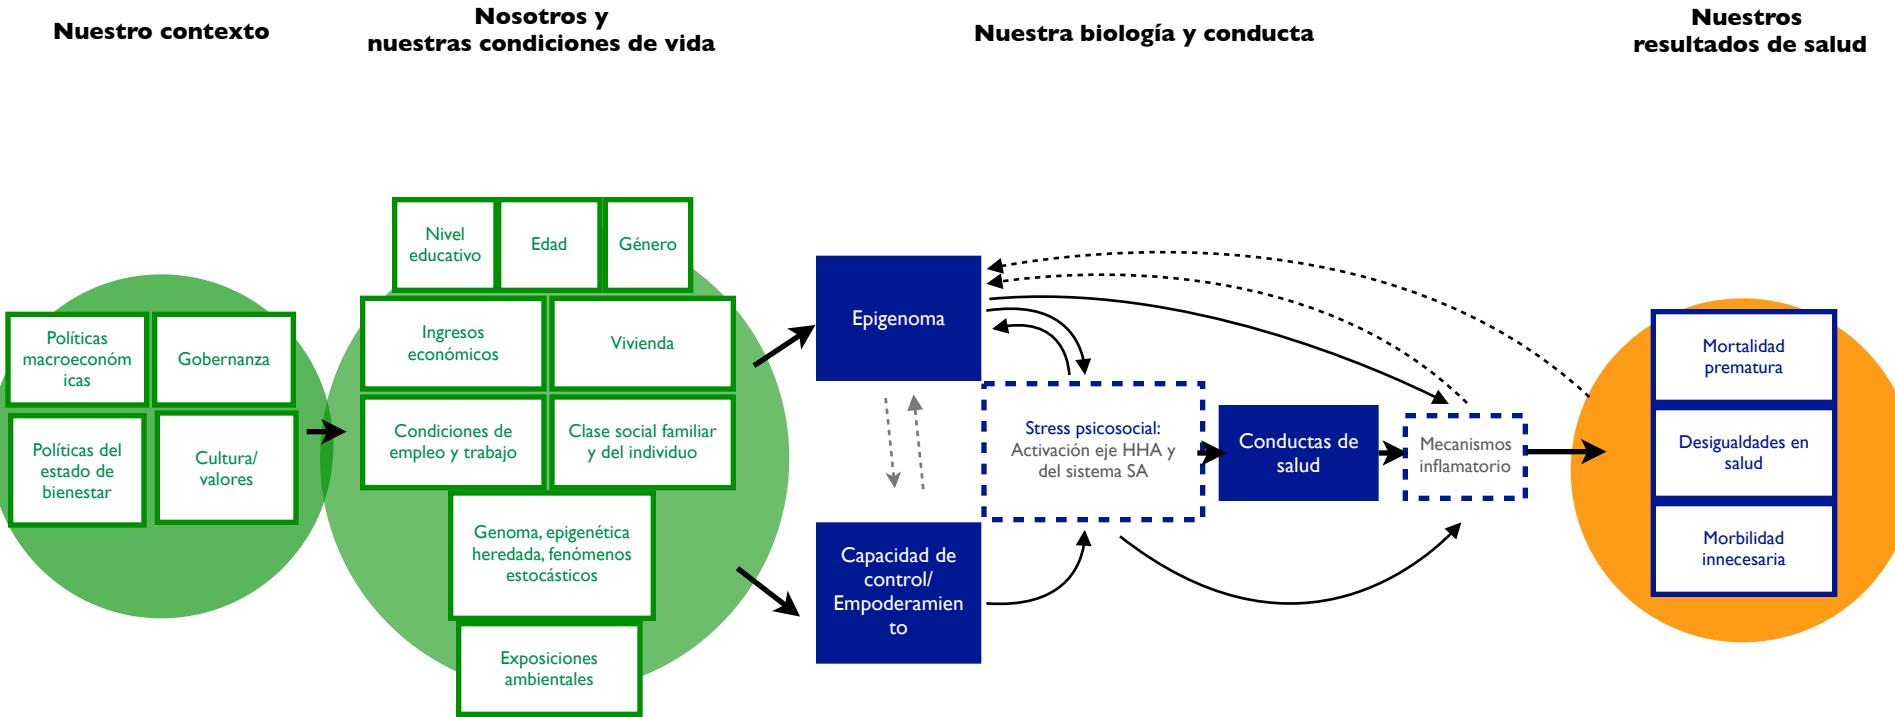

Background Epigenetic programming and epigenetic mechanisms driven by environmental factors are thought to play an important role in human health and ageing. Global DNA methylation has been postulated as an epigenetic marker for epidemiological studies as it is reflective of changes in gene expression linked to disease. How epigenetic mechanisms are affected by psychological, sociological and biological determinants of health still remains unclear. The aim of this study was to investigate the relationship

Socioeconomic Position, Co-Occurrence of Behavior-Related Risk Factors, and Coronary Heart Disease: the Finnish Public Sector Study

Mika Kivimäki, PhD, Debbie A. Lawlor, PhD, George Davey Smith, DSc, Anne Kouvousen, PhD, Marianna Virtanen, PhD, Marko Elovainio, PhD, Jussi Vahtera, MD

Coronary heart disease (CHD), a leading cause of morbidity and mortality in all Western countries, is more prevalent among lower socioeconomic position (SEP) groups than among groups that have higher SEP.^{1–7} Although the evidence of such a socioeconomic gradient in CHD is robust, the extent to which this gradient is the result of different distributions of coronary risk factors between SEP groups remains controversial. Several epidemiological studies suggested that most (60%–95%) of the CHD burden can be attributed to established risk factors: smoking, hypertension, diabetes, unfavorable cholesterol profile, and physical inactivity; appropriately, public health interventions target these risk factors to reduce the CHD epidemic.^{8–13} However, several studies that compare the magnitude of the socioeconomic gradient before and after adjustment for these risk factors suggest that they ex-

Objectives. We examined the associations between socioeconomic position, co-occurrence of behavior-related risk factors, and the effect of these factors on the relative and absolute socioeconomic gradients in coronary heart disease.

Methods. We obtained the socioeconomic position of 9337 men and 39255 women who were local government employees aged 17–65 years from employers' records (the Public Sector Study, Finland). A questionnaire survey in 2000–2002 was used to collect data about smoking, heavy alcohol consumption, physical inactivity, obesity, and prevalence of coronary heart disease (myocardial infarction or angina dia-

Results. The age-adjusted hazard ratio for low-income group was higher than for high-income group, and adjustment for risk factors did not attenuate this association. After adjustment for all other risk factors, all of the co-occurrence of measured risk factors was associated with an increased risk of myocardial infarction or angina dia-

Conclusions. Intervention programs that target individual risk factors may not completely remove the association between socioeconomic position and coronary heart disease risk. *Am J Public Health. 2007;97:874–879.*

Neighborhood Psychosocial Hazards and Cardiovascular Disease: The Baltimore Memory Study

Toms Augustin, MD, MPH, Thomas A. Glass, PhD, Bryan D. James, MBE, and Brian S. Schwartz, MD

The effect on health of the places in which people live—apart from individual, genetic, or lifestyle characteristics—is of increasing interest to researchers.¹ A new wave of research is examining the health consequences of various aspects of residential neighborhoods. Moving beyond the study of individual risk factors to the study of neighborhoods may be a key to understanding widening health disparities across racial/ethnic and sociodemographic groups.^{2,3}

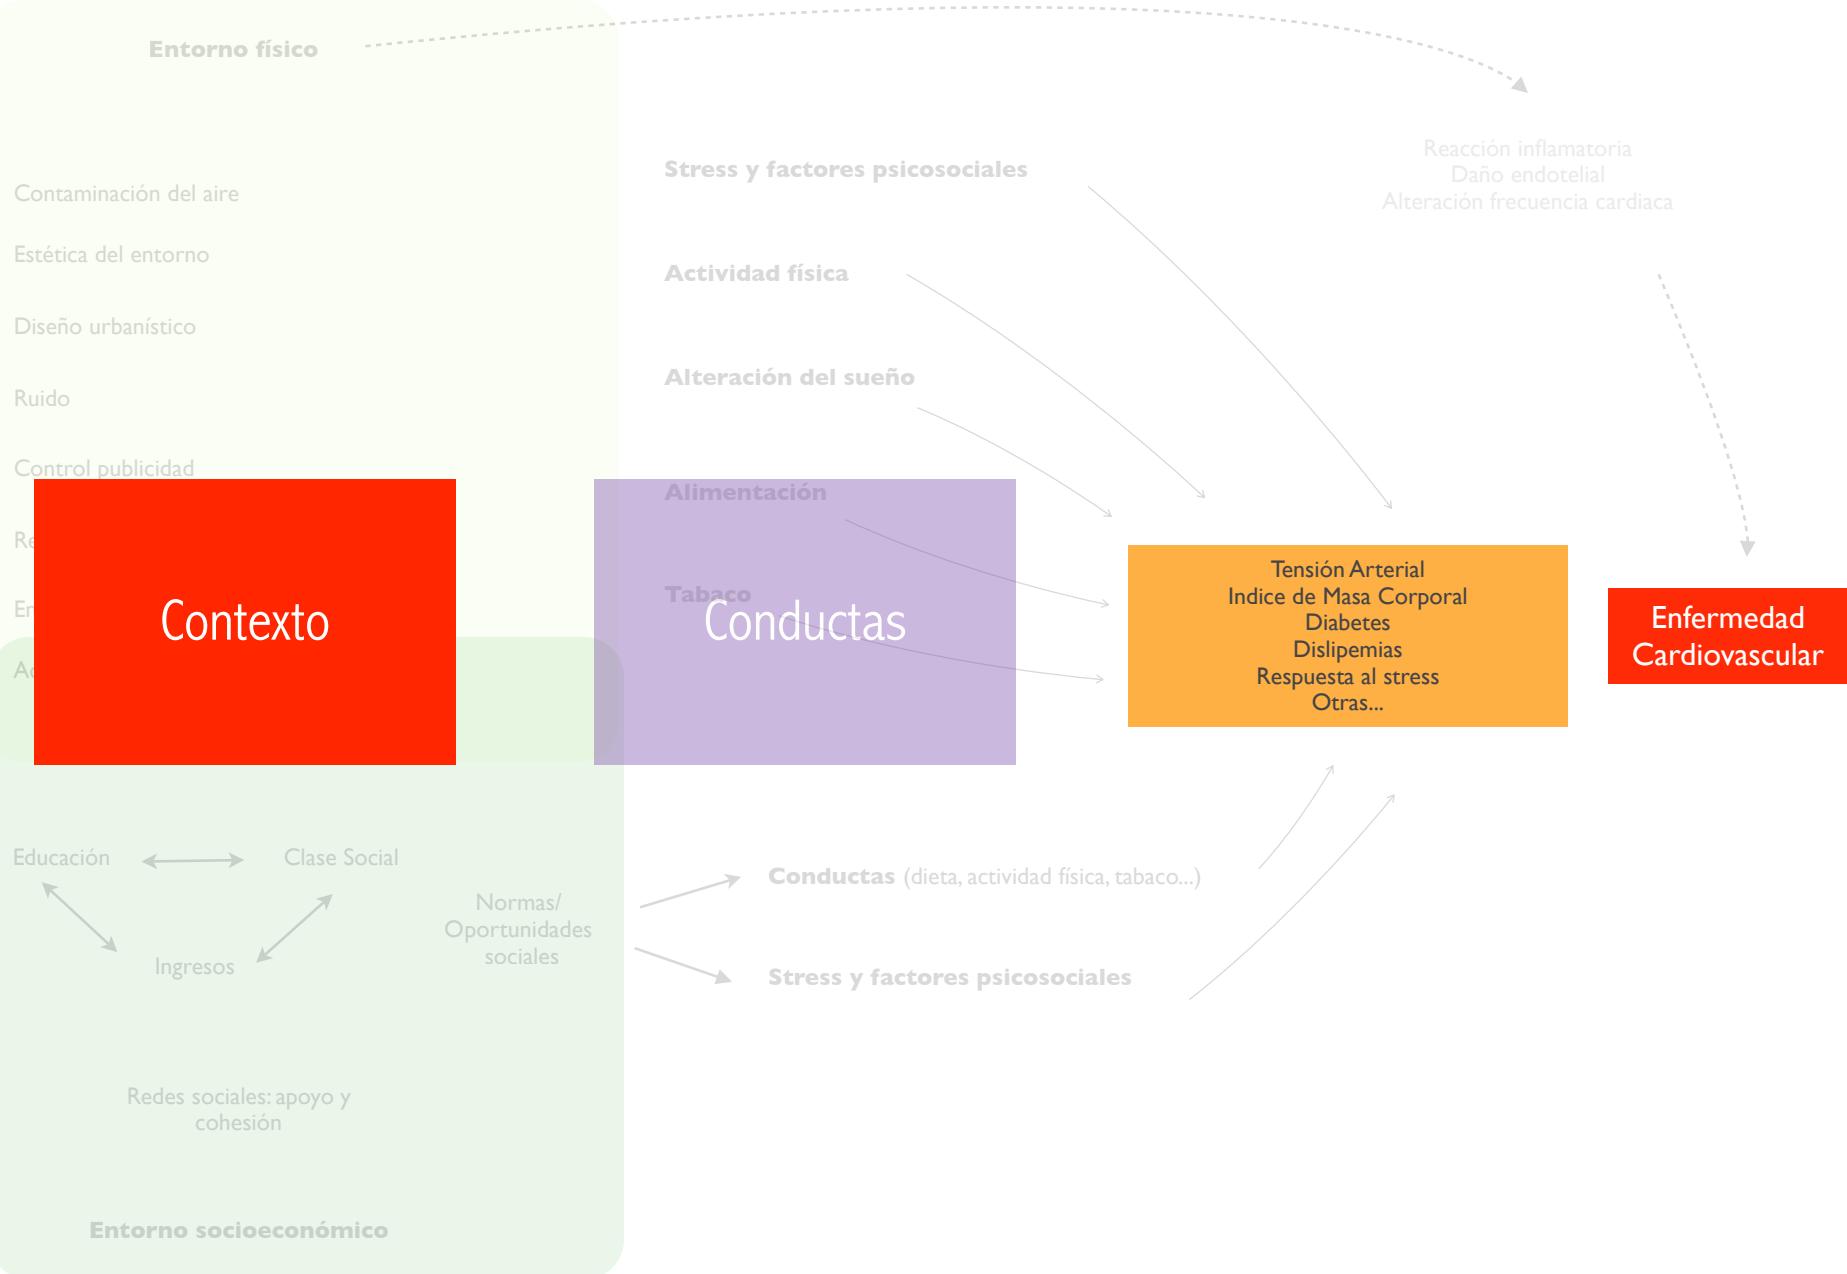

Many aspects of neighborhoods are hypothesized to influence cardiovascular disease (CVD) risk through several different and potentially interrelated mechanisms.^{4–6} Health behavior has received significant attention. Some data suggest that residents of socioeconomically deprived neighborhoods are more likely to engage in high-risk health behaviors, including inactivity,^{7,8} poor diet,⁹ illicit drug use,^{10,11} and smoking.¹² However, studies that found an association between neighborhood of residence and CVD after adjustment for

Objectives. We examined associations between cardiovascular disease and neighborhood psychosocial hazards, such as violent crime, abandoned buildings, and signs of incivility, to evaluate whether features of place are associated with older adult health.

Methods. We analyzed first-visit data from the Baltimore Memory Study of randomly selected residents aged 50 to 70 years ($n=1140$) of 65 contiguous neighborhoods in Baltimore, Maryland. We looked for associations between self-reports of history of selected cardiovascular diseases and scores on the 12-item neighborhood psychosocial hazards scale.

Results. After adjustment for established individual risk factors for cardiovascular disease, residents in neighborhoods with scores in the highest quartile of the psychosocial hazards scale had more than 4 times higher odds of a history of myocardial infarction and more than 3 times higher odds of myocardial infarction, stroke, transient ischemic attack, or intermittent claudication compared with residents living in neighborhoods scoring in the lowest quartile.

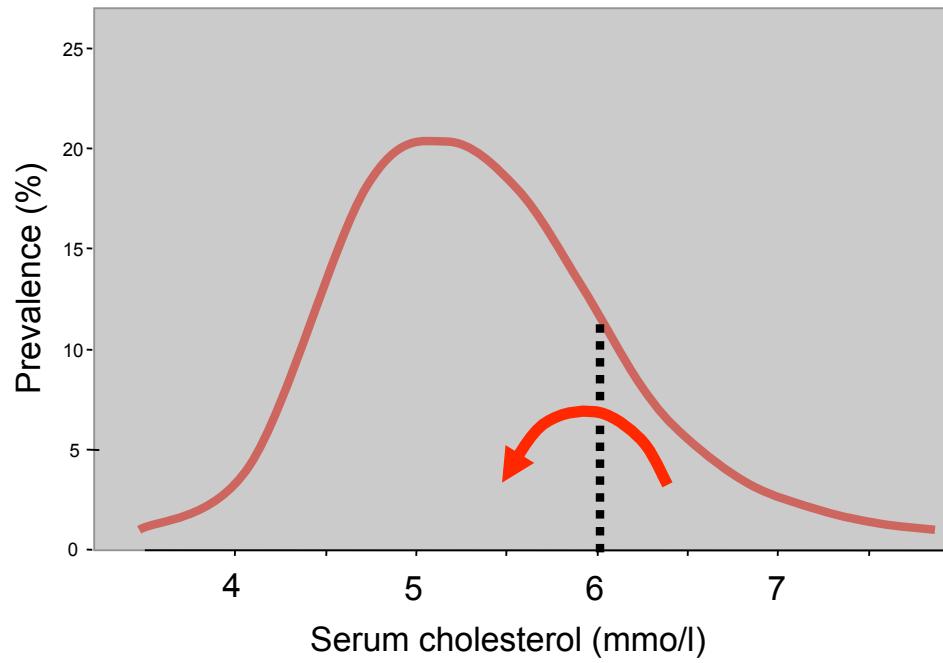

Conclusions. Neighborhood psychosocial hazards were significantly associated with self-reported cardiovascular disease after adjustment for individual-level risk factors. This is consistent with the hypothesis that environmental stress plays a role in the etiology of cardiovascular disease. *(Am J Public Health. 2008;98:1664–1670. doi:10.2105/AJPH.2007.125138)*

Clinical Preventive Medicine

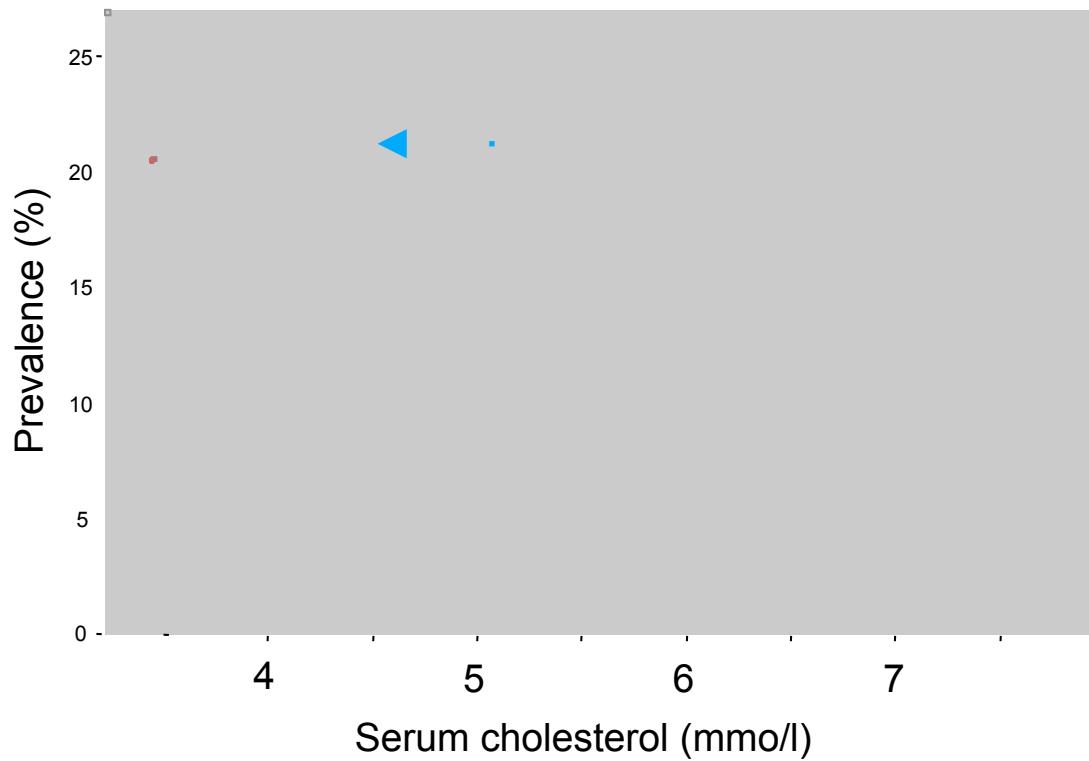

Focus on “high risk” individuals

- Screening
- Lipid lowering Rx for > cholesterol subjects

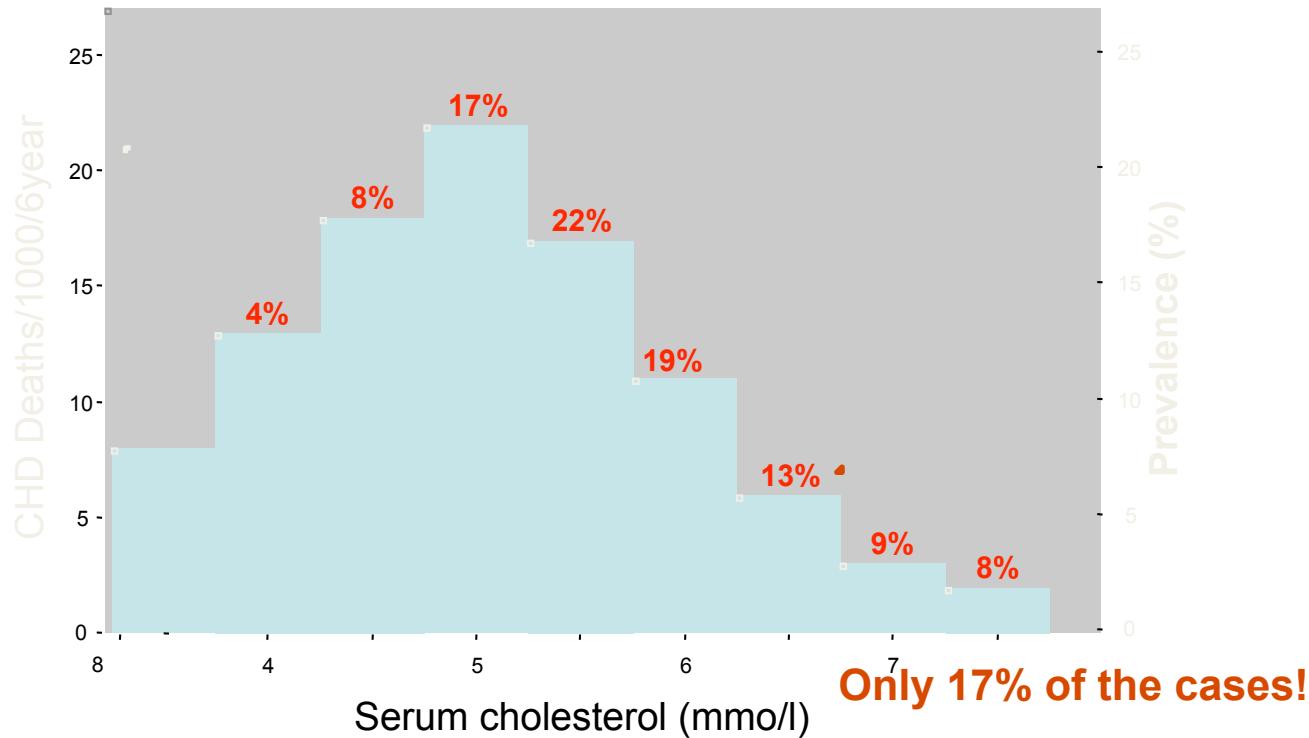

Population-Based Prevention

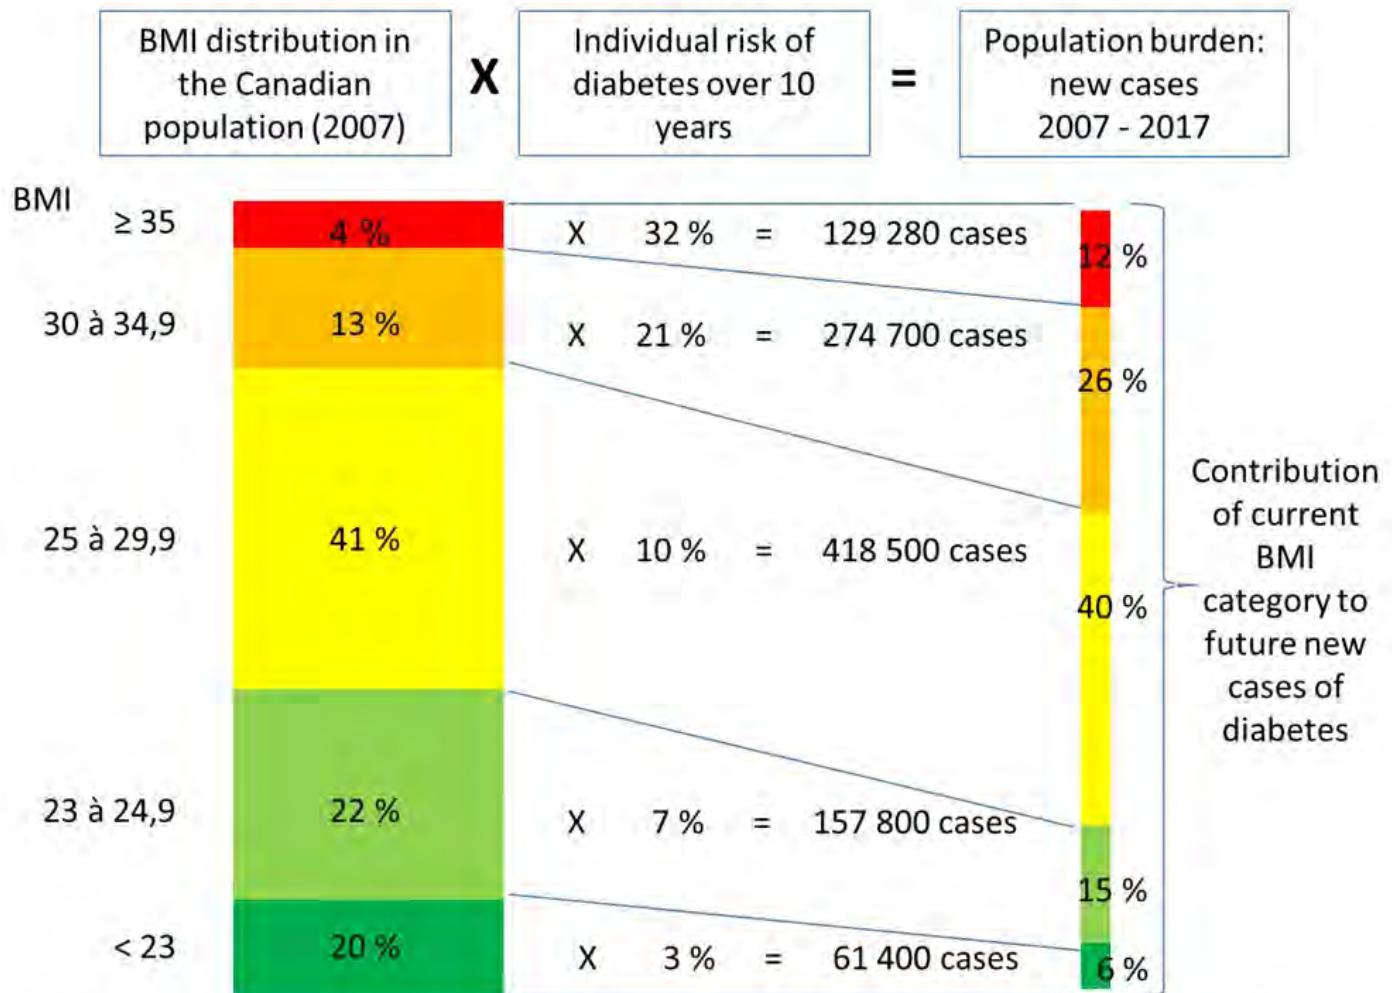

- Shifting the distribution of cholesterol in the population

Proportion of CHD cases attributable to elevated cholesterol within each cholesterol level category

$$\text{Pop Attributable Risk} = f[RR, \text{Prevalence}] = \frac{p(RR - 1)}{p(RR - 1) + 1}$$

ABSTRACT

The last decade has witnessed a surge in interest for policies to tackle health inequalities. Adequate theoretical development of policy models is needed to understand how to design and evaluate equity-oriented health policies. In this paper we review Graham's

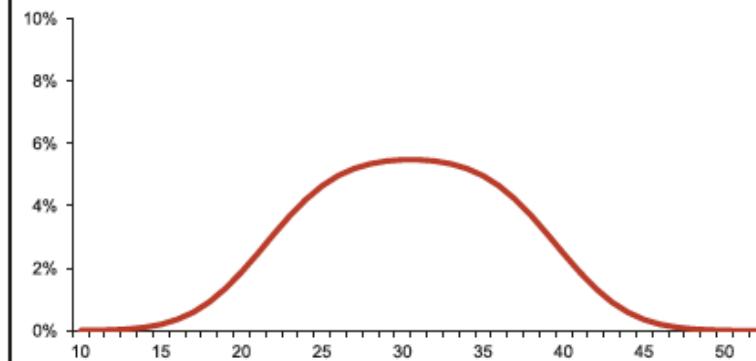

subpopulations or neighbourhoods. On the other hand, this approach on specific subpopulations has some policy disadvantages. First, it may undermine the politics of solidarity that is the key to maintaining support for public provision.¹⁰ Second, this approach does not commit itself to bringing levels
